

# MEMTTOO TIMELINE

The Memttoo is a product that utilizes conductive tattoo technology, nano-technology, holograms, and brain mapping to allow a user to save their memories and then recall and display them.

## DARPA Brain Interface project begins 2017

Darpa begins project that will allow a person to interface with their brain. In 2017 this is through metal leads in the brain but will lay the ground work for implanted brain computer chips.

## BRAIN MAPPING RESEARCH BEGINS 2019

The BRAIN initiative was initially funded with 100 million dollars to fully map the brain for the first time. This brain mapping project would lead to the necessary knowledge about the brain to utilize the neural interface technology being developed in at DARPA.

## Brain is fully mapped Around 2027

Functional NanoTechnology is now in consumer products. Brain interfaces have progressed and brain mapping is complete and private companies begin to develop technology using brain interfaces and brain mappings. Conductive tatoos are widely available.

## Memories can be saved to a server Around 2030

Private companies begin to develop technology using the neural interface and the brain map to create chips that allow record a user's life and saves the data to a server farm that can be recalled back to the user at will

## Memttoo become commercially available Around 2032

The brain chip and conductive tattoos product Memttoo is now commercially available.

## Memttoo Mass Production Around 2035

The Memttoo is on its way to becoming almost as ubiquitous as cell phones
